How does an airplane fly?

HOME KIDS AREA HOW DOES AN AIR...

Traction (Thrust): this force propels the aircraft in the air. The thrust is created by a Propeller or Jet engine.

Trail : The Air resistance, which tends to slow the forward motion of an Aircraft

Weight (Gravity) : This is the force which attracts all objects towards the earth.

Bearing Capacity: An upward force is created by a movement of air below the wing. The air flow thus becomes faster above the wing and more slowly below. This mechanism creates a difference in pressure that keeps a plane in flight.

The Traction forward opposes the Trail backwards.

The upward lift opposes the downward weight.
